

After you have installed a Kentico web project using the [Quick installation](#) or the [Custom installation](#), you can additionally modify its components using the Installer. You can add components that you did not install or remove components which you no longer need.

Adding and removing components after the installation

1. Run the Installer from **Windows Start -> All programs -> Kentico -> Kentico Installer**.
2. Click **Next** on the welcome screen of the Kentico installer.
3. Select your country, accept the license agreement, and click **Next**.
4. Click **Modify**.
5. Select the web project you want to modify.
 - Either select an already registered project from the list or select any other folder containing a Kentico web project using the **Select another** button.
6. Select the components you want to install and clear the checkboxes for components you want to uninstall.
7. You can also additionally install Windows services or register performance counters or event logging.
8. Click **Apply Changes**.

You can find more information about the **Register performance counters for Health Monitoring** and **Install Windows services for Scheduler and Health Monitoring** options in [Installing Kentico \(Questions and Answers\)](#).

The Installer now installs and uninstalls components according to your requirements.

Adding components to web application projects

If you use the installer to add components to a project of the **web application** type, you then need to open the project in Visual Studio and **Rebuild** the solution. Otherwise, you may encounter errors when using the functionality of the added components.
